

# 1000 Genomes and Population Genomics

As small groups separate, they evolve  
in isolation

How do the frequencies of alleles  
change over time?

- Selection
- Genetic Drift
- Hardy-Weinberg

Two alleles, Red (A) and Blue (a)  
Creates 3 genotypes AA, aa, and Aa

Gen 0

Two alleles, Red (A) and Blue (a)  
Creates 3 genotypes AA, aa, and Aa

Gen 0

Frequency of allele A;  $p$

Frequency of allele a:  $q$

$$p+q=1$$

Frequency of AA:  $D=p^2$

Frequency of Aa:  $H=2pq$

Frequency of aa:  $R=q^2$

Assume no selection and no mutation

Assume no migration and random mating

Assume infinite population sizes (no  
restrictions on numbers)

Two alleles, Red (A) and Blue (a)  
Creates 3 genotypes AA, aa, and Aa

Gen 0

Mating	Probability	Offspring Genotype frequencies		
		AA	Aa	aa
AA x AA	$D^2$	1	0	0
AA x Aa	2DH	$\frac{1}{2}$	$\frac{1}{2}$	0
AA x aa	2DR	0	1	0
Aa x Aa	$H^2$	$\frac{1}{4}$	$\frac{1}{2}$	$\frac{1}{4}$
Aa x aa	2HR	0	$\frac{1}{2}$	$\frac{1}{2}$
aa x aa	$R^2$	0	0	1
Total for Gen 1		$D'$	$H'$	$R'$

Mating	Probability	Offspring Genotype frequencies		
		AA	Aa	aa
AA x AA	D <sup>2</sup>	1	0	0
AA x Aa	2DH	½	½	0
AA x aa	2DR	0	1	0
Aa x Aa	H <sup>2</sup>	¼	½	¼
Aa x aa	2HR	0	½	½
aa x aa	R <sup>2</sup>	0	0	1
Total for Gen 1		D'	H'	R'

$$D' = D^2 + \frac{2DH}{2} + \frac{H^2}{4} = \left(D + \frac{H}{2}\right)^2 = (p^2 + p(1-p))^2 = (p^2 + p - p^2) = p^2$$

$$R' = \frac{H^2}{4} + \frac{2HR}{2} + R^2 = \left(R + \frac{H}{2}\right)^2 = (q^2 + q(1-q))^2 = (q^2 + q - q^2) = q^2$$

$$H' = \frac{2DH}{2} + 2DR + \frac{H^2}{2} + \frac{2HR}{2} = 2\left(D + \frac{H}{2}\right)\left(R + \frac{H}{2}\right) = 2pq$$

**Genotypes  
are stable  
over time**

Andrews, C. (2010) The Hardy-Weinberg Principle. *Nature Education Knowledge* 3(10):65

Two alleles, Red (A) and Blue (a)  
Creates 3 genotypes AA, aa, and Aa

Gen 0

Frequency of allele A;  $p$

Frequency of allele a:  $q$

$$p+q=1$$

Frequency of AA:  $D=p^2$

Frequency of Aa:  $H=2pq$

Frequency of aa:  $R=q^2$

Assume no selection and no mutation

Assume no migration and random mating

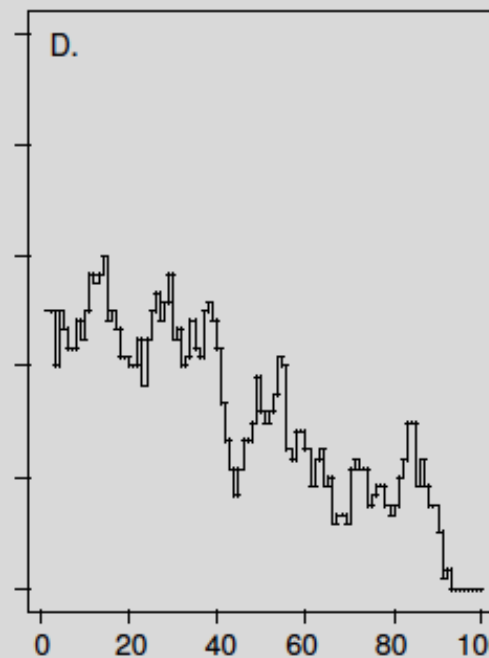

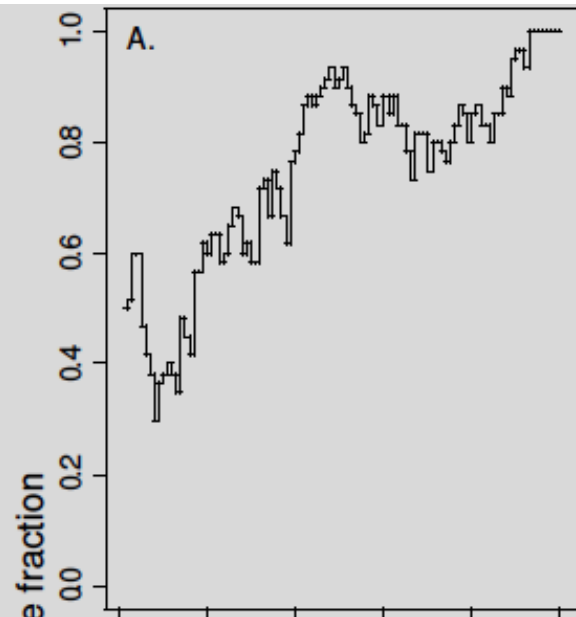

~~Assume infinite population sizes (no  
restrictions on numbers)~~

Two alleles, Red (A) and Blue (a)  
Creates 3 genotypes AA, aa, and Aa

**Genetic Drift**

Number of Generations

If not infinite number of offspring, then random fluctuations in number of alleles can cause dramatic changes in allele frequency

These drifts are more pronounced in a smaller population

$$h(n) = \left(1 - \frac{1}{2N}\right)^n h(0).$$

Heterozygosity is lost at a geometric rate with the number of generations (n) that depends on the number of individuals (N)

Two alleles, Red (A) and Blue (a)  
Creates 3 genotypes AA, aa, and Aa

Gen 0

Frequency of allele A;  $p$

Frequency of allele a:  $q$

$$p+q=1$$

Frequency of AA:  $D=p^2$

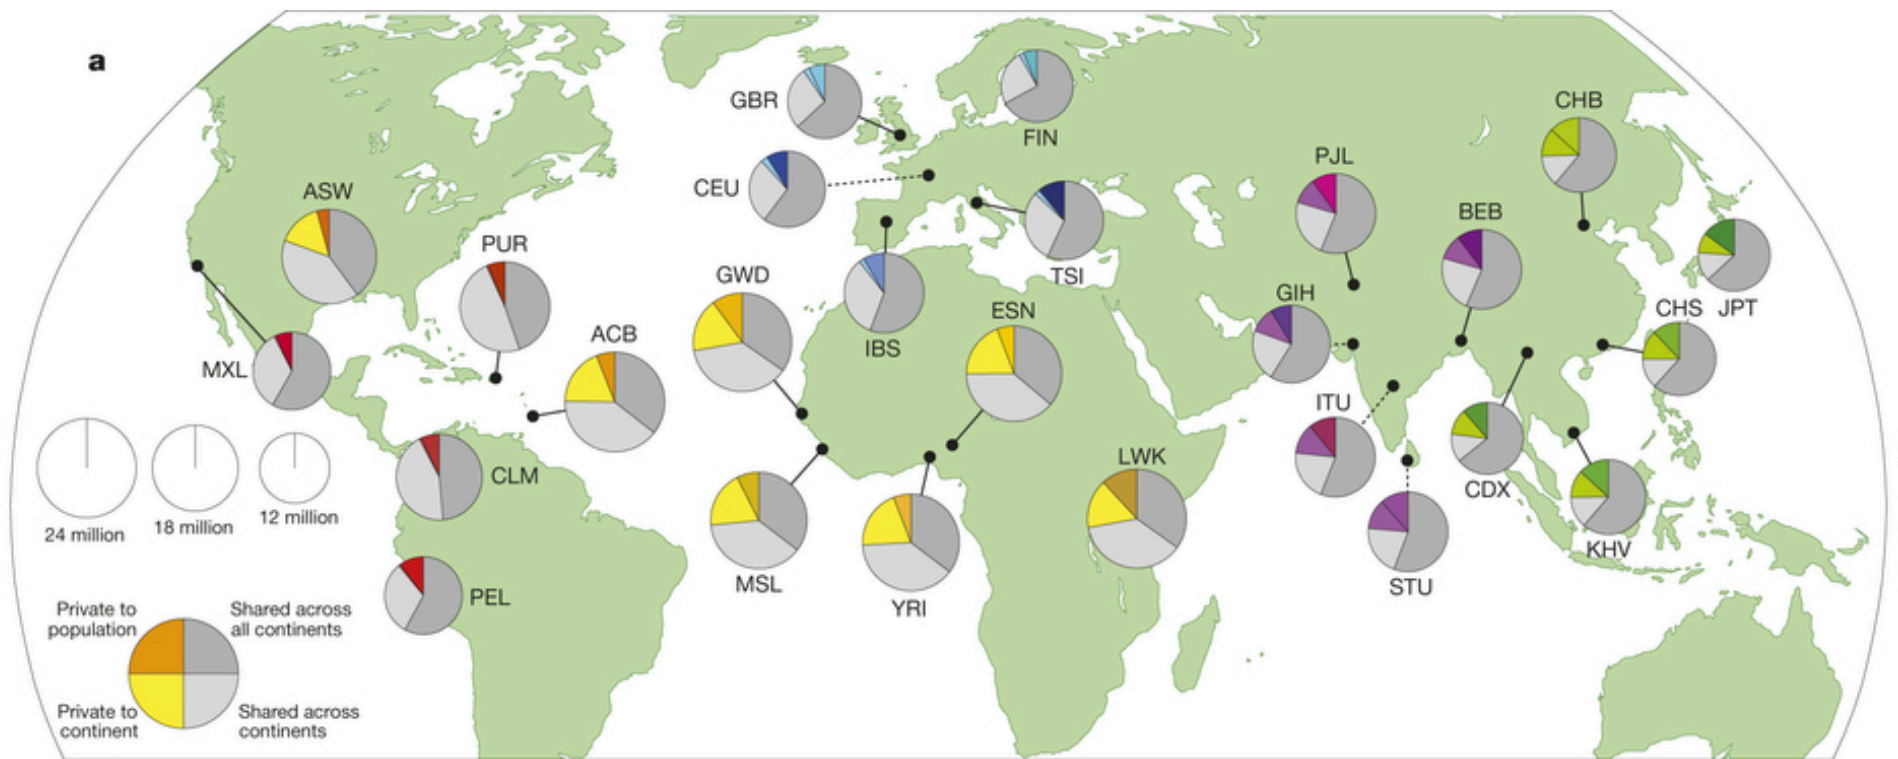

Frequency of Aa:  $H=2pq$

Frequency of aa:  $R=q^2$

**Assume no selection and no mutation**

**Assume no migration and random mating**

~~Assume infinite population sizes (no  
restrictions on numbers)~~

The 1000 Genomes Project Consortium; *Nature* **526**, 68–74 (01 October 2015) doi:10.1038/nature15393

**b**

The 1000 Genomes Project Consortium; *Nature* **526**, 68–74 (01 October 2015) doi:10.1038/nature15393

Why does the higher level of variants per genome support the out of Africa hypothesis of human evolution and migration?

The 1000 Genomes Project Consortium; *Nature* **526**, 68–74 (01 October 2015) doi:10.1038/nature15393

The populations not in Africa are more similar to each other than those within Africa, indicating a common set of ancestors from Africa (founder population), while within Africa, the least common ancestor is further back, evolutionarily.

The 1000 Genomes Project Consortium; *Nature* **526**, 68–74 (01 October 2015) doi:10.1038/nature15393

What's going on with these populations? Why do they seem to split the non-African and African patterns?

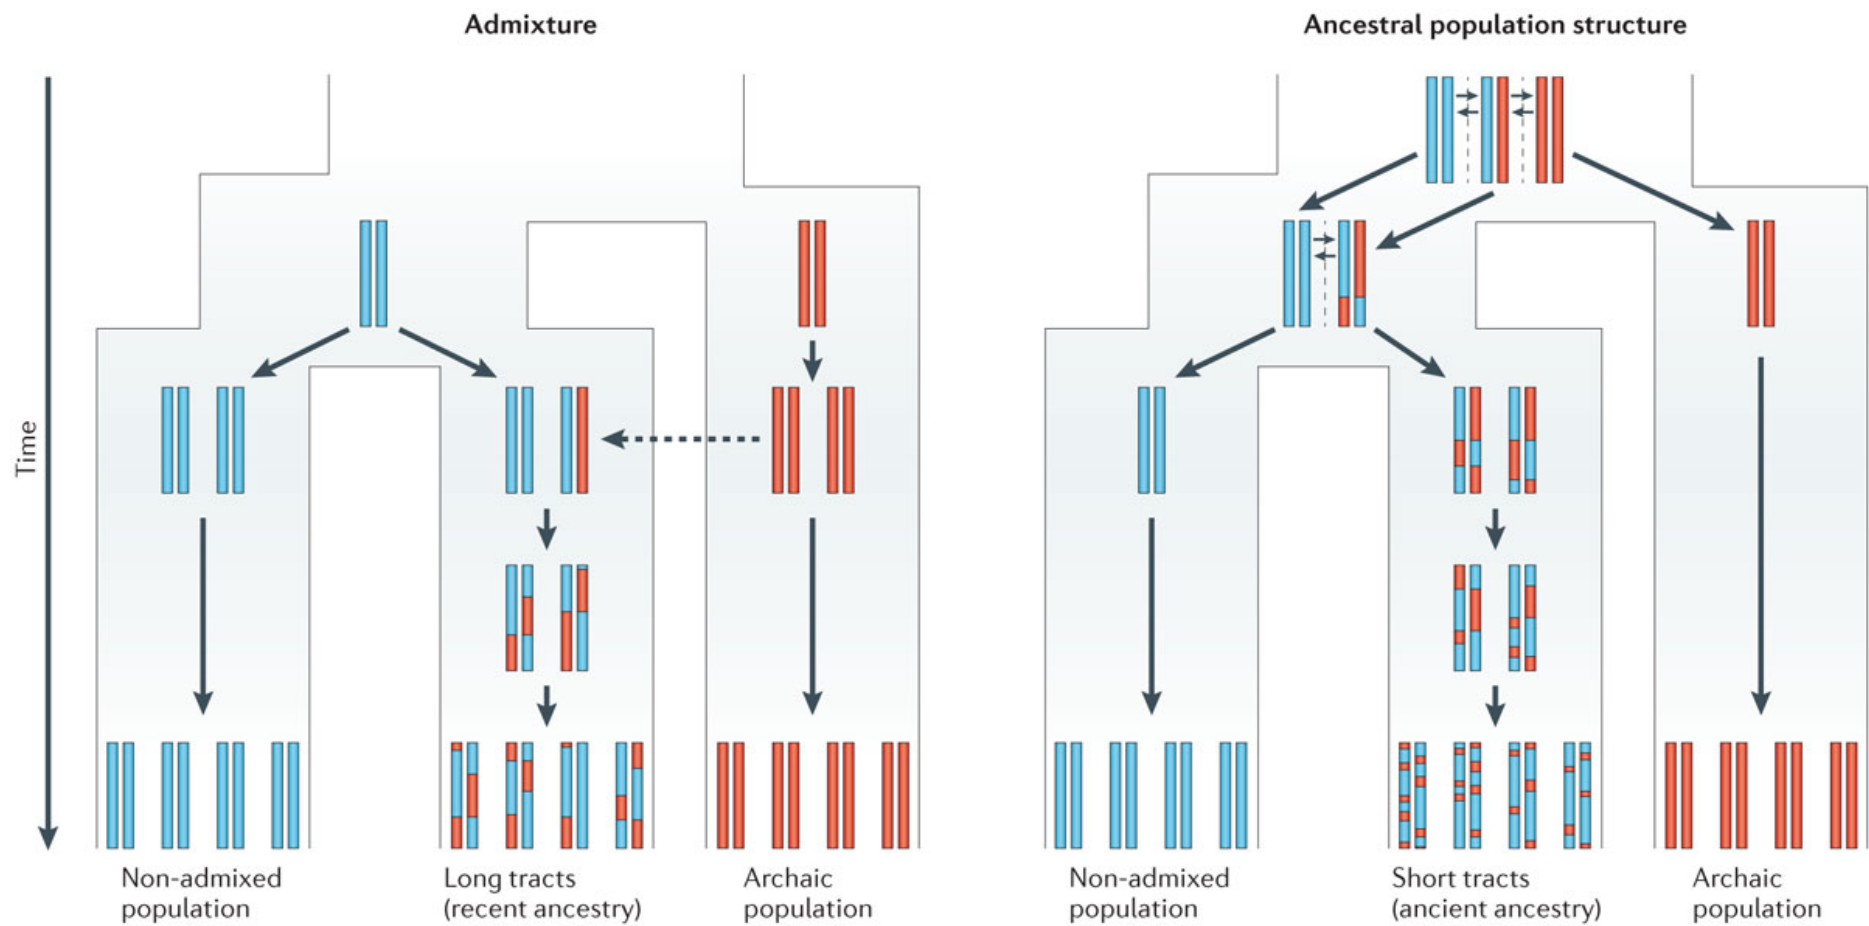

The 1000 Genomes Project Consortium; *Nature* **526**, 68–74 (01 October 2015) doi:10.1038/nature15393

What's going on with these populations? Why do they seem to split the non-African and African patterns?

They are the populations that have the highest admixture of African with non-African. Mostly places that were central to the African slave trade.

Which chromosome is not admixed or recombined? Is there other DNA in a cell that also transmits without change from generation to generation?

Which chromosome is not admixed or recombined? Is there other DNA in a cell that also transmits without change from generation to generation?

The Y chromosome doesn't have a pair, so can not recombine, and therefore doesn't get admixed.

Mitochondrial DNA is transmitted intact from the maternal line

Because the allele probabilities change during evolution/migration/drift, different populations will have different probabilities of a given allele.

Population 1

Population 2

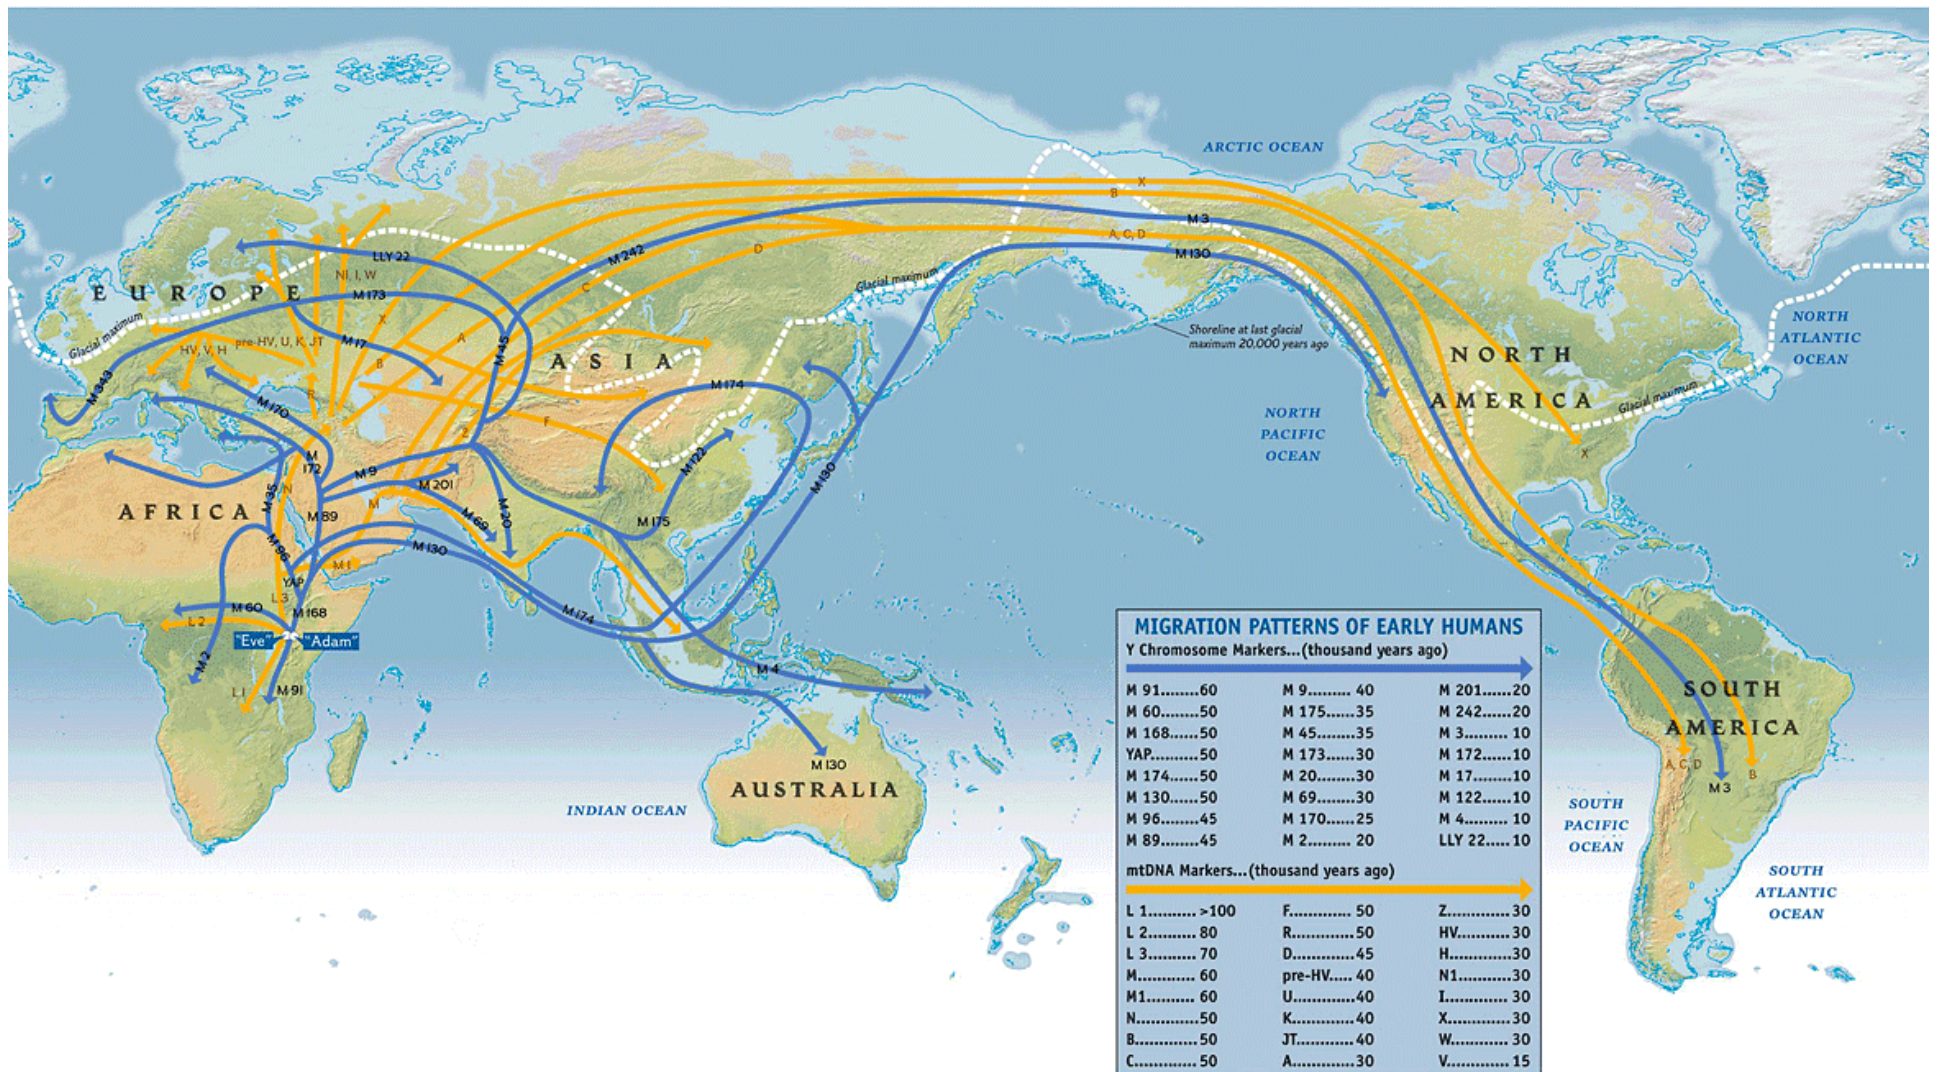

Population 3

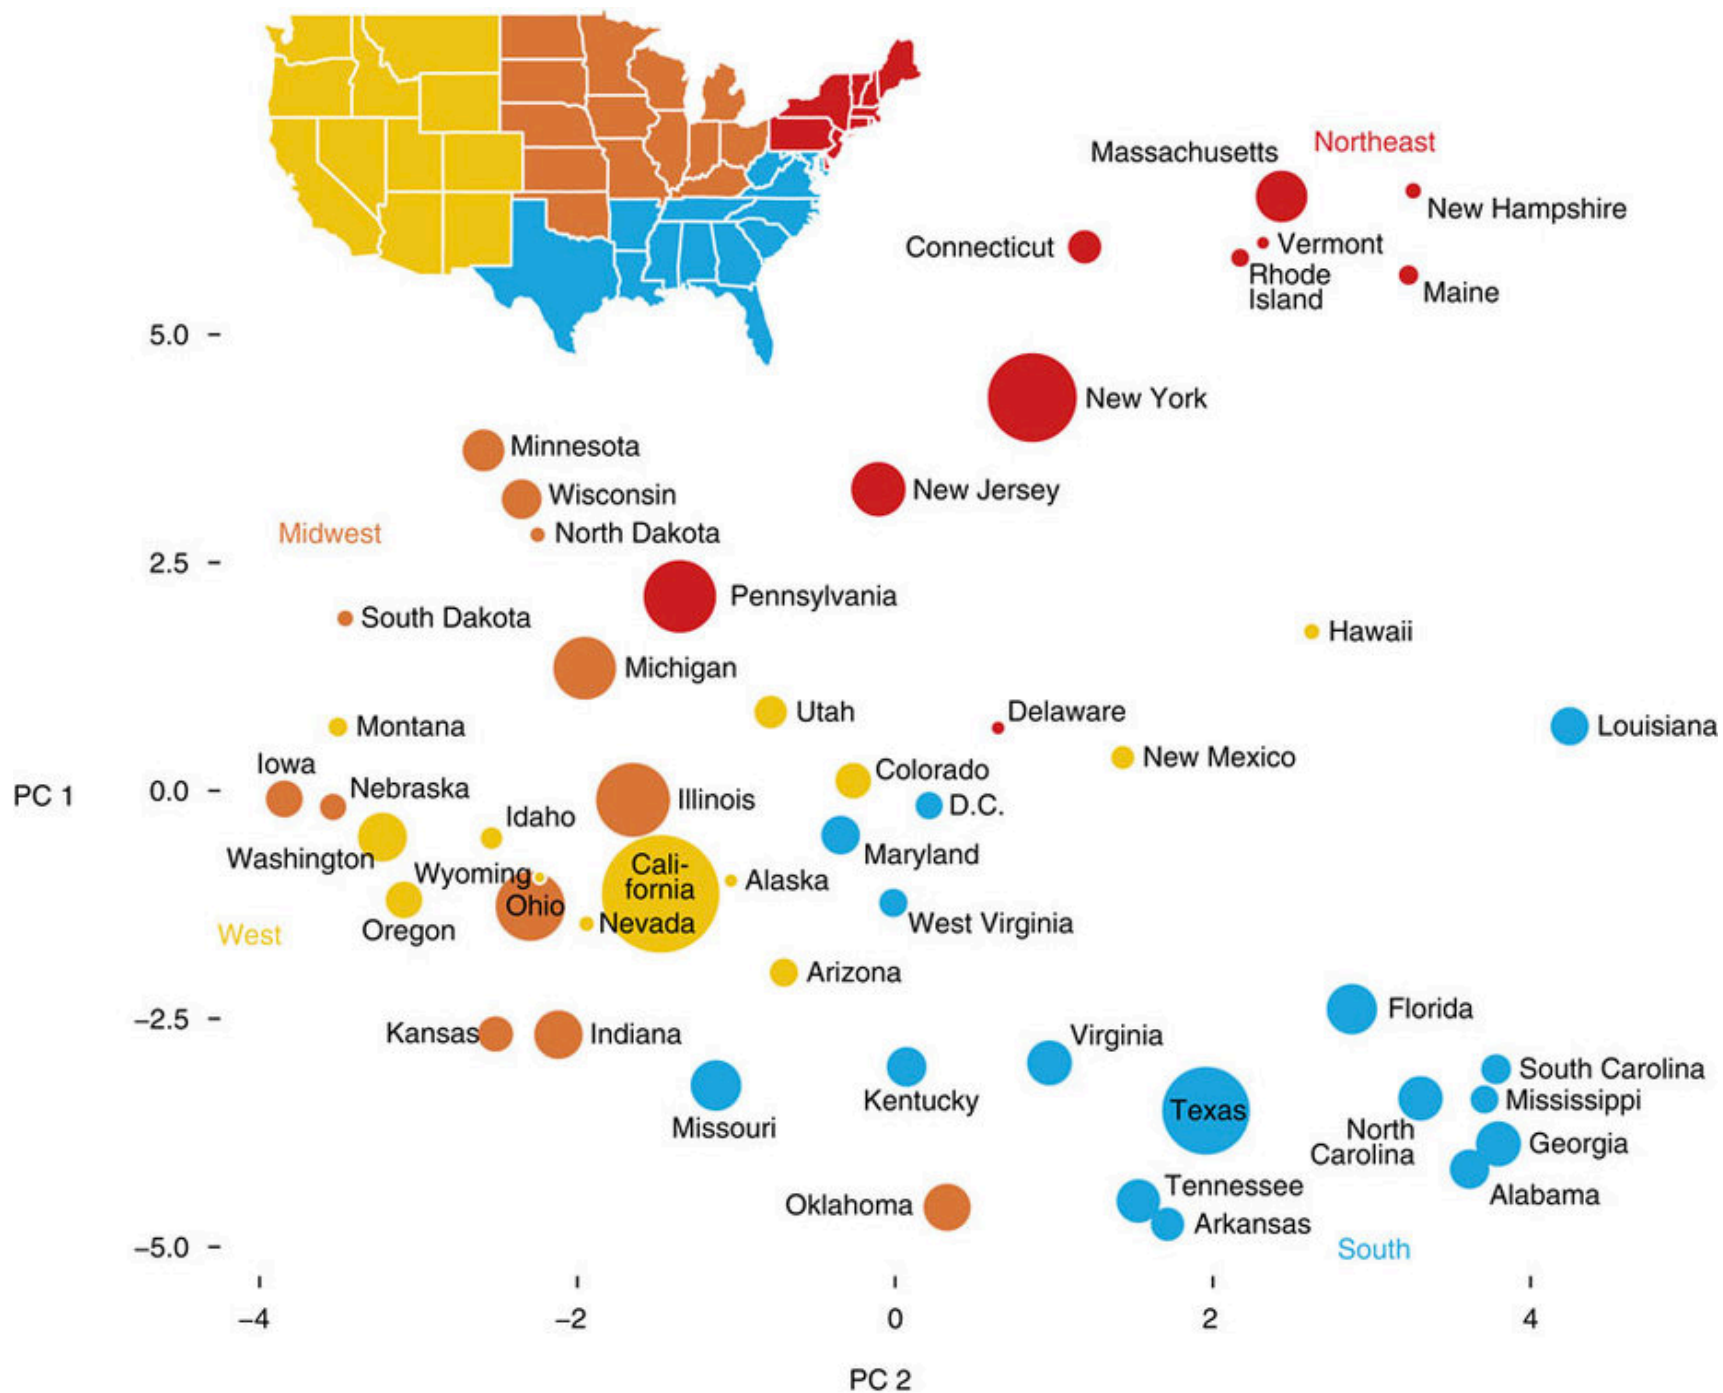

Allows us to predict ancestry, but also gets in the way of determining what alleles associate with a phenotype

**a****Construct network from IBD.**

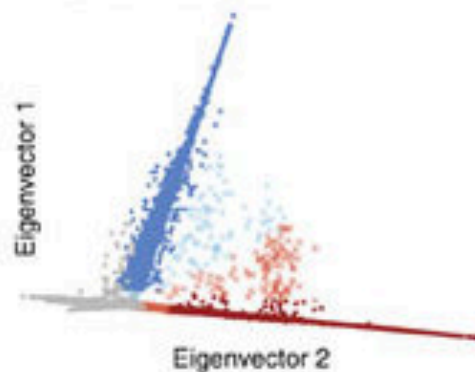

Join vertex pairs (genotyped samples) if IBD > 12 cM.  
Edge weights are a function of total detected IBD.

**b****Detect network clusters.**

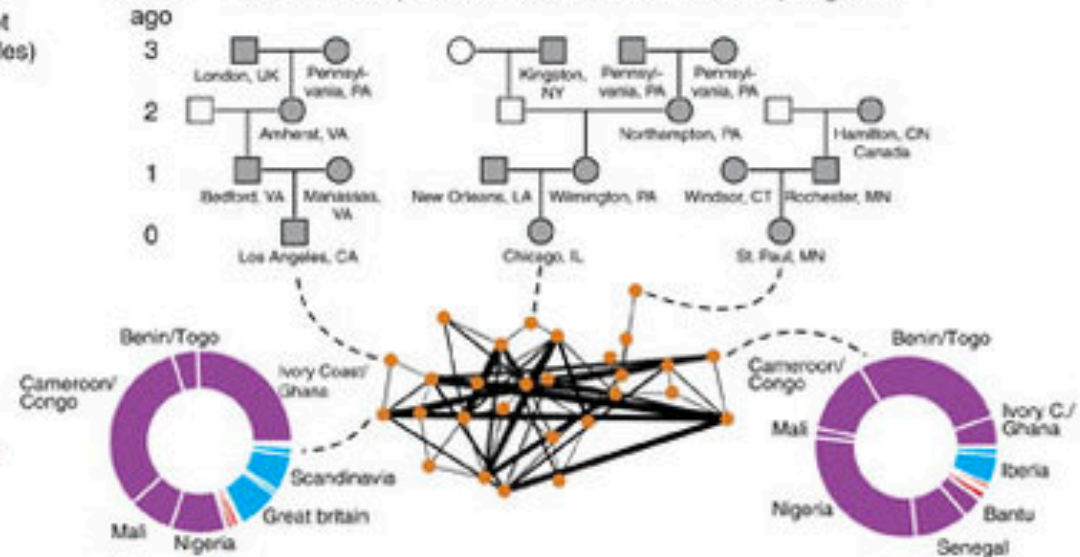

Recursively identify disjoint sets that maximize the modularity of the network. (Here one level of clustering hierarchy is shown.)

**c**

Identify subsets of the clusters that separate in the spectral embedding. Spectral embedding is computed from eigen-decomposition of Laplacian matrix. In the plot below, we identify "stable subsets" (filled circles) of the blue and red clusters.

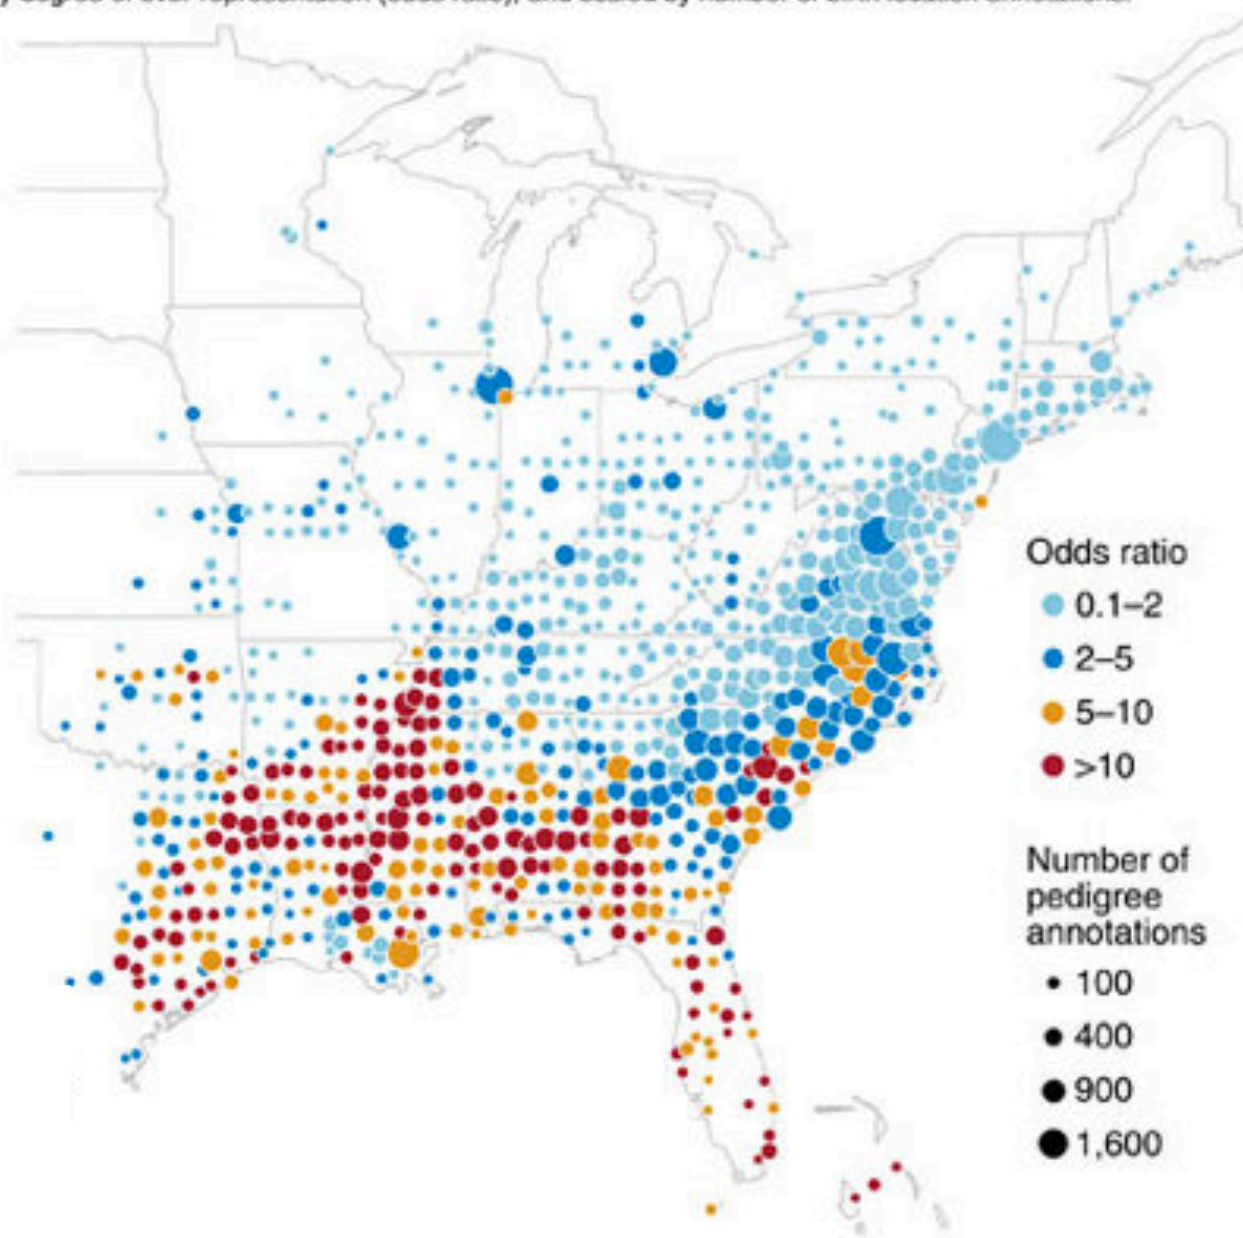

**d****Annotate each cluster with two kinds of data:**

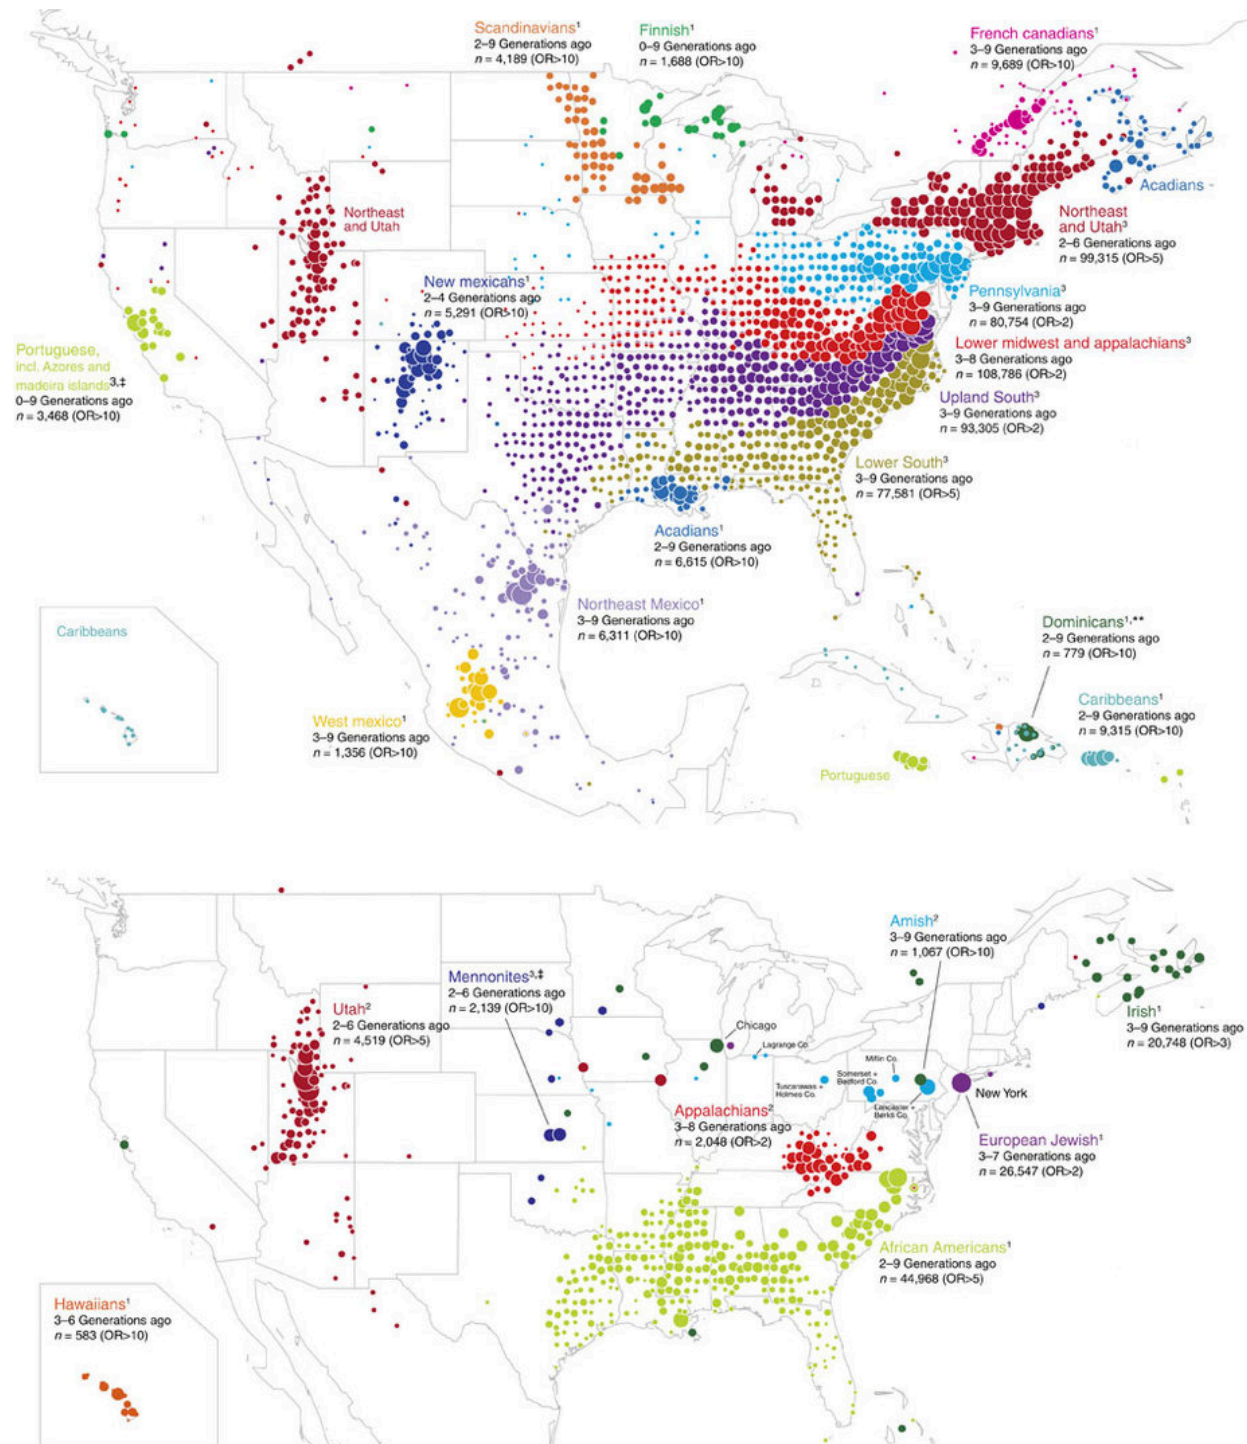

- In all samples, global admixture of 20 populations (donut charts);
- For some samples, birth locations of ancestors in pedigrees.

**e**

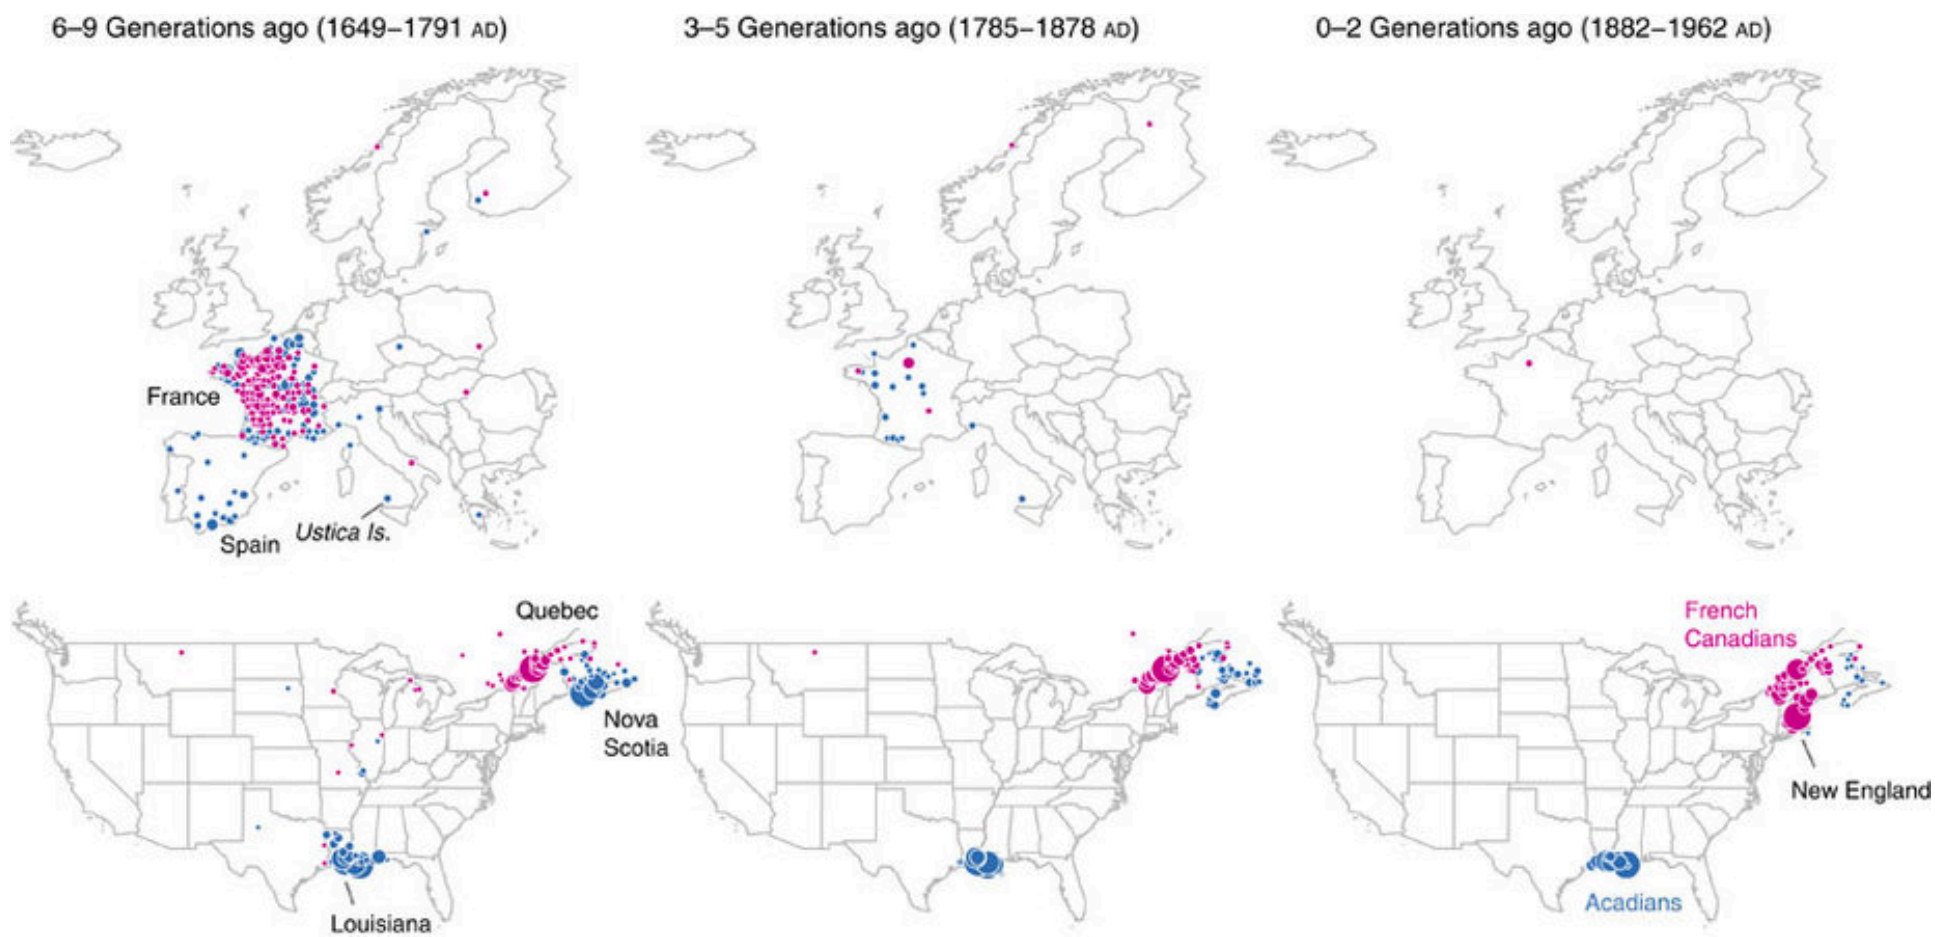

Visualize geographic distribution of ancestral birth locations in each cluster.  
Map below shows birth locations of ancestors in the African American cluster. Locations are colored by degree of over-representation (odds ratio), and scaled by number of birth location annotations.

Han, E, et al; *Nature Communications* **8**, Article number: 14238 (2017); doi:10.1038/ncomms14238

Far more information than in 1000 Genome Project! Greater diversity in some ancestries

# Difficulties in their data

- Some populations had poor ancestry data
  - African–Americans
  - Ashkenazi Jews
- Data still very biased toward European ancestry
- The way they biased the data to increase resolution in recent ancestry, omits populations that are less distinctve/more admixed
  - African-Americans communities in Northern cities for generations

# Implications of this study

- Exciting that we can trace migrations so tightly
- Private data set
  - Ancestry.com is not a public repository
    - Company grew out of LDS genealogy projects
  - They got their data by having people pay for their own data

# Summary

# Next Class
